## Multilayered nanostructures as devices

- Sandwich of metal-barriermetal with current moving perpendicular to the planes
- Nonlinear current-voltage characteristics
- Josephson junctions, diodes, thermoelectric coolers, spintronic devices, etc.
- Band insulators: AlO<sub>x</sub> MgO
- Correlated materials: FeSi, SrTiO<sub>3</sub> and other oxides.
- Near MIT:  $V_2O_3$ ,  $Ta_xN$

#### Theoretical Approaches (charge transport)

- Ohm's law:  $R_n = \rho L/A$ , holds for bulk materials
- Landauer approach: calculate resistance by determining the reflection and transmission coefficients for quasiparticles moving through the inhomogeneous device  $(R_n=h/2e^2*[1-T]/T)$
- Works well for ballistic metals, diffusive metals, and infinitesimally thin tunnel barriers ("delta function potentials").
- Real tunnel barriers have a finite thickness---the quasiparticle picture breaks down inside the insulating barrier; not clear that Landauer approach still holds.
- As the barrier thickness approaches the bulk limit, the transport crosses over to being thermally activated in an insulator and is no longer governed by tunneling.

Need a theory that can incorporate all forms of transport (ballistic, diffusive, incoherent, thermally activated, and strongly correlated) on an equal footing

A self-consistent recursive Green's function approach called **inhomogeneous dynamical mean field theory** (first developed by Potthoff and Nolting) can treat all of these different kinds of transport.

#### Our model

The metallic leads can be ballistic normal metals, meanfield theory ferromagnets, or BCS superconductors.

Scattering in the barrier is included via charge scattering with "annealed defects" (as in the Falicov-Kimball model) or via the Coulomb interaction (as in the Hubbard model)

Scattering can also be included in the leads if desired, but we don't do so here.

Spinless Falicov-Kimball Model and Hubbard Model

$$H = -\frac{t}{2\sqrt{d}} \sum_{\langle i,j \rangle} c^{\dagger}_{i} c_{j} + E \sum_{i} w_{i} + U \sum_{i} c^{\dagger}_{i} c_{i} w_{i}$$
  
mobile spin -> 
$$U$$

•exactly solvable model in the local approximation using dynamical mean field theory.

•possesses homogeneous, commensurate/incommensurate CDW and SDW phases, phase segregation, and **metal-insulator transitions**.

•A self-consistent recursive Green's function approach solves the inhomogeneous many-body problem (Potthoff-Nolting algorithm).

Algorithm is iterated until a self-consistent solution is achieved

# Half-filling and the particle-hole symmetric metal-insulator transition ...

# Metal-insulator transition (half-filling)

The Falicov-Kimball model has a **metal**insulator transition that occurs as the correlation energy U is increased. The bulk interacting DOS shows that a **pseudogap** phase first develops followed by the opening of a true gap above U=4.9 (in the bulk). Note: the FK model is not a Fermi liquid in its metallic state since the lifetime of excitations is finite.

J. K. Freericks, Georgetown University, Yalta NATO ARW talk, 2007

#### Near the MIT (U=6)

J. K. Freericks, Georgetown University, Yalta NATO ARW talk, 2007

### L=a (Single plane barrier, FK model)

Local DOS on the central barrier plane. Note how the upper and lower Hubbard bands form for the Mott transition, but there is always substantial subgap DOS from the localized barrier states. This DOS arises from quantum-mechanical tunneling and has a metallic shape for large U!

J. K. Freericks, Georgetown University, Yalta NATO ARW talk, 2007

### L=a (Single plane barrier, Hubbard model)

Local DOS on the central barrier plane. Note the similarity with the results for the FK model, except for the coherence peak forming at the lowest energies (because the Hubbard model is a Fermi liquid). We believe the coherence peak will be present for all U values at T=0 (these calculations are for room temperature), but can be extremely narrow for large U.

J. K. Freericks, Georgetown University, Yalta NATO ARW talk, 2007

### U=6 (small-gap insulator) DOS

### Friedel oscillations induced by interface

### U=6 Correlated insulator

DOS has exponential tails, but never vanishes in the "gap"; the exponential decay has the same characteristic length for all barrier thicknesses.

J. K. Freericks, Georgetown University, Yalta NATO ARW talk, 2007

Charge transport and the generalized Thouless energy ...

### Junction resistance

- The linear-response resistance can be calculated in equilibrium using a Kubo-Greenwood approach.
- We must work in real space because there is no translational symmetry.
- R<sub>n</sub> is calculated by inverting the isothermal conductivity matrix and summing all matrix elements of the inverse.

## Junction resistance (derivation)

- Maxwell's equation gives j<sub>i</sub>=∑<sub>j</sub>σ<sub>ij</sub>E<sub>j</sub> where the index denotes a plane in the layered device.
  (The field at plane j causes a current at plane i.)
- Taking the matrix inverse gives  $\mathbf{E}_i = \sum_j \sigma^{-1}_{ij} \mathbf{j}_j$ ; but the current is conserved, so  $\mathbf{j}$  does not depend on the planar index j.
- Calculating the voltage gives  $V=a\sum_{i}E_{i}=a\sum_{ij}\sigma^{-1}_{ij}j$ , so the resistance-area product is  $R_{n}A=a\sum_{ij}\sigma^{-1}_{ij}$

#### Resistance versus resistivity

J. K. Freericks, Georgetown University, Yalta NATO ARW talk, 2007

#### Resistance for U=6 (correlated insulator)

Resistance here shows the tunneling plateaus clearly, and a strong temperature dependence in the incoherent regime.

J. K. Freericks, Georgetown University, Yalta NATO ARW talk, 2007

## Thouless energy

• The **Thouless energy** measures the quantum energy associated with the time that an electron spends inside the barrier region of width L (Energy extracted from the resistance).

$$E_{Th} = \hbar / t_{Dwell}$$

• A **unifying form** for the Thouless energy can be determined from the resistance of the barrier region and the electronic density of states:

$$E_{Th} = \frac{\hbar}{2e^2 \int d\omega N(\omega) \frac{-df(\omega)}{d\omega} R_N AL}$$

• This form produces both the **ballistic**  $E_{Th} = \hbar v_F^N / \pi L$  and the **diffusive**  $E_{Th} = \hbar D / L^2$  forms of the Thouless energy.

# Thouless energy II

• The **resistance** can be considered as the **ratio** of the Thouless energy to the quantum-mechanical level spacing  $\Delta_E$  (with  $R_Q = h/2e^2$  the quantum unit of resistance)

$$R_n = R_Q \frac{\Delta_E}{2\pi E_{Th}}$$

• The inverse of the level spacing is related to the density of states of the barrier via

$$\Delta_E^{-1} = VN(\mu)$$

• Generalizing the above relation to an insulator by

$$\Delta_E^{-1} = AL \int d\omega N(\omega) \left[ -\frac{df(\omega)}{d\omega} \right]$$

gives the general form for the Thouless energy.

#### Temperature dependence

U=6 FK model

The Thouless energy determines the transition from tunneling to incoherent transport as a function of temperature! *Note that the crossover temperature is not simply related to the energy gap!* 

Josephson junctions, figure-ofmerit, and the generalized Thouless energy ...

#### Critical current density

The current through the junction is increased as a phase gradient is placed over the leads. The current increases to Bulk a maximal value, called the critical current of the junction. Here we show the critical current versus the thickness of the barrier.

#### Figure of Merit

The Thouless energy determines the figure of merit once it becomes the smallest energy scale in the problem. The quasiclassical approach seems to hold all they way up to the MIT. Beyond that, the behavior appears to become nonuniversal, but with similar qualitative features.

# Particle-hole asymmetry is necessary for thermoelectric devices ...

Using a scanning transmission electron microscope with electron energy-loss spectroscopy, one can directly measure the electronic charge at each plane of a strongly correlated multilayered nanostructure. Left are experimental results by Varela et al. on YBCO/LCMO heterostructures, right is a simple theory for a correlated nanostructure.

We employ a semiclassical treatment to handle the electronic charge reconstruction. We allow charge to be rearranged on different planes, as determined by the electrochemical potential at a given plane site, and then determine the classical Coulomb potential from planes of net charge, with dielectric constants that can vary from plane to plane.

# Coulomb potential

The Coulomb potential develops a kink at locations where the dielectric constant changes (i.e. at the interfaces), and it goes to zero far from the interface due to overall conservation of charge.

As the screening length decreases, the total charge that is rearranged gets smaller for a fixed chemical potential mismatch of the bulk materials.

J. K. Freericks, Georgetown University, Yalta NATO ARW talk, 2007

#### DOS with electronic charge reconstruction

Changing the band offsets creates particle-hole asymmetry in the DOS.

J. K. Freericks, Georgetown University, Yalta NATO ARW talk, 2007

Thermal transport in a multilayered nanostructure

## Heat Current Conservation

- Unlike the charge current, the heat current need not be conserved in a multilayered nanostructure.
- The experimental conditions will determine the boundary conditions for the heat current, which need to be employed to solve for the heat transport.
- We describe the Seebeck effect here.

### Heat transport equations

In the presence of field and temperature gradients, the charge and heat currents satisfy:

$$j_i = e^2 \sum_j L^{11}_{ij} E_j - e \sum_j L^{12}_{ij} (T_{j+1} - T_{j-1})/2a$$

$$j_{Qi} = \sum_{j} L^{21}_{ij} E_j - \sum_{j} L^{22}_{ij} (T_{j+1} - T_{j-1})/2a$$

Where the L matrices are found from the **Jonson-Mahan theorem** (current and heatcurrent correlation functions in real space)

#### Seebeck effect

In the Seebeck effect, we isolate the device and work with an open circuit. *Hence there is no heat created or destroyed in the steady state (i.e., the heat current is conserved) and the total charge current vanishes*:

The E field becomes  $E_j = \sum_{jk} (L^{11})^{-1}{}_{ij}L^{12}{}_{jk} (T_{k+1}-T_{k-1})/2a$ The temperature gradients become  $\sum_j M^{-1}{}_{ij}j_Q = -(T_{i+1}-T_{i-1})/2a; M = -L^{21}(L^{11})^{-1}L^{12}+L^{22}$ 

Hence,  $\Delta T = \sum_{ij} M^{-1}_{ij} j_Q$ ,  $\Delta V = -a \sum_{ij} [(L^{11})^{-1} L^{12} M^{-1}]_{ij} j_Q$ , and the Seebeck coefficient is  $S = \Delta V / \Delta T = a \sum_{ij} [(L^{11})^{-1} L^{12} M^{-1}]_{ij} / \sum_{ij} M^{-1}_{ij}$ 

Note the weighting by the matrix *M*, which is different for a nanostructure than in the bulk, where that factor cancels as can be seen from the convolution theorem!

# Thermal transport created from electronic charge reconstruction

### Seebeck effect

Numerically we evaluate the Seebeck coefficient for two particlehole symmetric bulk materials with an electronic charge reconstruction. Seebeck **The Seebeck** effect can become quite large!

# Figure of merit

The figure-ofmerit can also become large, and is bigger than 1 for small band offsets. The phonon thermal conductance can dramatically reduce the figure-of-merit though.

# Conclusions

In this talk I have covered a number of topics in strongly correlated nanostructures. These included the following: (i) DOS and charge transport in the particle-hole symmetric case, when the barrier is tuned through the Mott transition; (ii) a description of transport, including the tunneling to Ohmic crossover, via a generalized Thouless energy; (iii) an application to Josephson junctions and the figure-of-merit; (iv) electronic charge reconstruction, and how to selfconsistently determine the screened dipole layers that lead to Schottky-like barriers; and (v) thermal transport, the Seebeck effect, and the figure-of-merit.

The interplay between inhomogeneity and electronelectron correlations leads to interesting new phenomena, that could have wide-ranging applications.
